Contents

1 Techniques

1.1 Various algorithm techniques

```
Recursion
Divide and conquer
        Finding interesting points in N log N
Greedy algorithm
        Scheduling
        Max contigous subvector sum
        Invariants
        Huffman encoding
Graph theory
        Dynamic graphs (extra book-keeping)
        Breadth first search
        Depth first search
        * Normal trees / DFS trees
        Dijkstra's algoritm
        MST: Prim's algoritm
        Bellman-Ford
        Konig's theorem and vertex cover
        Min-cost max flow
        Lovasz toggle
        Matrix tree theorem
        Maximal matching, general graphs
        Hopcroft-Karp
        Hall's marriage theorem
        Graphical sequences
        Floyd-Warshall
        Eulercykler
        Flow networks
        * Augumenting paths
```

2 Data Structures

2.1 Fenwick Tree (Binary Index Tree)

```
// Fenwick Tree / Binary Indexed Tree
ll bit[N];

void add(int p, int v) {
  for (p += 2; p < N; p += p & -p) bit[p] += v;
}

ll query(int p) {
  ll r = 0;
  for (p += 2; p; p -= p & -p) r += bit[p];
  return r;
}
```

2.2 Segment Tree

```
// Segment Tree (Range Query and Range Update)
// Update and Query - O(log n)

int n, v[N], lz[4*N], st[4*N];

void build(int p = 1, int l = 1, int r = n) {
  if (l == r) { st[p] = v[l]; return; }
  build(2*p, l, (l+r)/2);
  build(2*p+1, (l+r)/2+1, r);
  st[p] = min(st[2*p], st[2*p+1]); // RMQ -> min/max, RSQ -> +
}

void push(int p, int l, int r) {
  if (lz[p]) {
    st[p] = lz[p];
    // RMQ -> update: = lz[p],          increment: += lz[p]
    // RSQ -> update: = (r-l+1)*lz[p], increment: += (r-l+1)*lz[p]
    if(l!=r) lz[2*p] = lz[2*p+1] = lz[p]; // update: =, increment +=
    lz[p] = 0;
  }
}

int query(int i, int j, int p = 1, int l = 1, int r = n) {
  push(p, l, r);
  if (l > j or r < i) return INF; // RMQ -> INF, RSQ -> 0
```

```
  if (l >= i and j >= r) return st[p];
  return min(query(i, j, 2*p, l, (l+r)/2),
             query(i, j, 2*p+1, (l+r)/2+1, r));
  // RMQ -> min/max, RSQ -> +
}

void update(int i, int j, int v, int p = 1, int l = 1, int r = n) {
  push(p, l, r);
  if (l > j or r < i) return;
  if (l >= i and j >= r) { lz[p] = v; push(p, l, r); return; }
  update(i, j, v, 2*p, l, (l+r)/2);
  update(i, j, v, 2*p+1, (l+r)/2+1, r);
  st[p] = min(st[2*p], st[2*p+1]); // RMQ -> min/max, RSQ -> +
}
```

2.3 Segment Tree (from Lyon)

```
//Segment Tree
#include <iostream>
#define N (1<<18)

using namespace std;
//int find(vector <int>& C, int x){return (C[x]==x) ? x : C[x]=find(C, C[x]);} C++
//int find(int x){return (C[x]==x)?x:C[x]=find(C[x]);}
typedef pair<int,int> ii;
ii arb[N]={{0,0}};
int n,m,a,b,v;
char type;

void update(int node,int l,int r,int a,int b,int val,int p)
{
        if(a<=l && r<=b)
        {
                arb[node].first=val;
                arb[node].second=p;
        }
        else
        {
                int mid=(l+r)/2;
                if(a<=mid)
                        update(node*2,l,mid,a,b,val,p);
                if(b>mid)
                        update(2*node+1,mid+1,r,a,b,val,p);
        }
}

pair<int,int> search(int node,int l,int r,int a)
{
        if(a==l && a==r)
        {
                return arb[node];
        }
        else
        {
                int mid=(l+r)/2;
                ii cur;
                if(a<=mid)
                        cur=search(2*node,l,mid,a);
                else
                        cur=search(2*node+1,mid+1,r,a);
                if(cur.second<arb[node].second)
                        return arb[node];
                else
                        return cur;
        }
}
```

2.4 Sparse Table

```
const int N;
const int M; //log2(N)
int sparse[N][M];

void build() {
  for(int i = 0; i < n; i++)
    sparse[i][0] = v[i];

  for(int j = 1; j < M; j++)
    for(int i = 0; i < n; i++)
      sparse[i][j] =
        i + (1 << j - 1) < n
        ? min(sparse[i][j - 1], sparse[i + (1 << j - 1)][j - 1])
        : sparse[i][j - 1];
}

int query(int a, int b){
  int pot = 32 - __builtin_clz(b - a) - 1;
  return min(sparse[a][pot], sparse[b - (1 << pot) + 1][pot]);
}
```

2.5 Treap (Cartesian Tree)

```
// Treap (probabilistic BST)
// O(logn) operations (supports lazy propagation)

mt19937_64 llrand(random_device{}());

struct node {
  int val;
  int cnt, rev;

```

5.21 Strongly Connected Components (Kosaraju)

```
/*****************************************************************************
* KOSARAJU'S ALGORITHM (GET EVERY STRONGLY CONNECTED COMPONENTS (SCC))       *
* Description: Given a directed graph, the algorithm generates a list of every    *
* strongly connected components. A SCC is a set of points in which you can reach  *
* every point regardless of where you start from. For instance, cycles can be     *
* a SCC themselves or part of a greater SCC.                                      *
* This algorithm starts with a DFS and generates an array called "ord" which      *
* stores vertices according to the finish times (i.e. when it reaches "return").  *
* Then, it makes a reversed DFS according to "ord" list. The set of points        *
* visited by the reversed DFS defines a new SCC.                                  *
* One of the uses of getting all SCC is that you can generate a new DAG (Directed *
* Acyclic Graph), easier to work with, in which each SCC being a "supernode" of   *
* the DAG.                                                                        *
* Time complexity: O(V+E)                                                         *
* Notation: adj[i]:   adjacency list for node i                                   *
*           adjt[i]:  reversed adjacency list for node i                          *
*           ord:      array of vertices according to their finish time            *
*           ordn:     ord counter                                                 *
*           scc[i]:   supernode assigned to i                                     *
*           scc_cnt:  amount of supernodes in the graph                           *
*****************************************************************************/

14 Strings

14.1 Knuth-Morris-Pratt Algorithm (fast pattern matching)

```
def KnuthMorrisPratt(text, pattern):

    '''Yields all starting positions of copies of the pattern in the text.
Calling conventions are similar to string.find, but its arguments can be
lists or iterators, not just strings, it returns all matches, not just
the first one, and it does not need the whole text in memory at once.
Whenever it yields, it will have read the text exactly up to and including
the match that caused the yield.'''

    # allow indexing into pattern and protect against change during yield
    pattern = list(pattern)

    # build table of shift amounts
    shifts = [1] * (len(pattern) + 1)
    shift = 1
    for pos in range(len(pattern)):
        while shift <= pos and pattern[pos] != pattern[pos-shift]:
            shift += shifts[pos-shift]
        shifts[pos+1] = shift

    # do the actual search
    startPos = 0
    matchLen = 0
    for c in text:
        while matchLen == len(pattern) or \
              matchLen >= 0 and pattern[matchLen] != c:
            startPos += shifts[matchLen]
            matchLen -= shifts[matchLen]
        matchLen += 1
        if matchLen == len(pattern):
            yield startPos
```

14.2 Rabin-Karp Algorithm (multiple pattern matching)

```
# d is the number of characters in input alphabet
d = 256

# pat  -> pattern
# txt  -> text
# q    -> A prime number

def search(pat, txt, q):
    M = len(pat)
    N = len(txt)
    i = 0
    j = 0
```

```
p = 0    # hash value for pattern
t = 0    # hash value for txt
h = 1

# The value of h would be "pow(d, M-1)%q"
for i in xrange(M-1):
    h = (h*d)%q

# Calculate the hash value of pattern and first window
# of text
for i in xrange(M):
    p = (d*p + ord(pat[i]))%q
    t = (d*t + ord(txt[i]))%q

# Slide the pattern over text one by one
for i in xrange(N-M+1):
    # Check the hash values of current window of text and
    # pattern if the hash values match then only check
    # for characters on by one
    if p==t:
        # Check for characters one by one
        for j in xrange(M):
            if txt[i+j] != pat[j]:
                break
                j+=1
                # if p == t and pat[0...M-1] = txt[i, i+1, ...i+M-1]
                if j==M:
                    print "Pattern found at index " + str(i)

            # Calculate hash value for next window of text: Remove
            # leading digit, add trailing digit
            if i < N-M:
                t = (d*(t-ord(txt[i])*h) + ord(txt[i+M]))%q

                # We might get negative values of t, converting it to
                # positive
                if t < 0:
                    t = t+q

# Driver program to test the above function
txt = "GEEKS FOR GEEKS"
